

# Generation Zoning and Nodal exchange rates

---

Warwick, 29th July 2008

**nationalgrid**

# Recapping

---

- ◆ One to one TEC exchange Zones have been identified, and these zones are mainly
  - ◆ Existing Generation Centres
  - ◆ Demand Centres
  - ◆ Radial spurs
- ◆ Possibility of inter-zonal TEC exchange?
- ◆ Possibility of nodal TEC exchange?

# Setting TEC Exchange Ratio

## – Things to Consider

---

- ◆ Short-term or long term?
- ◆ Physical limit based or financial cost based?
- ◆ Transparency
- ◆ Stability
- ◆ Simplicity
- ◆ Accuracy
- ◆ ...

# Transmission Rights - Overview

---

- ◆ Locational Marginal Cost (LMP) based, point-to-point rights
  - ◆ A transaction  $A \rightarrow B$  can be converted to  $A \rightarrow \text{hub} + B \rightarrow \text{hub}$
  - ◆ Bid-based, accommodating multiple constraints
  - ◆ Volatile and less transparent prices
  - ◆ Complicated

# Transmission Rights - Overview

---

- ◆ Flowgate based, branch-by-branch rights
  - ◆ Physical limits visible - transparent
  - ◆ One transaction requires a bundle of rights
  - ◆ Volatile: 1.5 billion updates of ATCs in less than a year!
  - ◆ Even more complicated to implement

# Transmission Rights - Overview

---

- ◆ Zonal transmission charges based on a fixed scenario and MWkm
  - ◆ Transparent
  - ◆ Simple to implement
  - ◆ Stable
  - ◆ Not suitable for short-term (typically day-ahead or hour-ahead) right definitions

## TEC Exchange Ratio – 1:1 or 1:k

---

- ◆ 1:1—suitable for bid-based and transaction-based model
- ◆ 1:k—only suitable for bid-based model
- ◆ Unlikely to get consistent exchange rates- i.e.  $A \rightarrow C$  does not equal to  $A \rightarrow B + B \rightarrow C$

# Points of discussion

---

- ◆ Nodal exchange rates MWkm methodology
- ◆ Nodal exchange rates MW (NZM) methodology
- ◆ Considering nodes with existing generation or signed applications only
- ◆ Number of trading parties and zonal TEC to measure size of zone
- ◆ Intra-zonal trading coupled with either
  - ◆ nodal exchange rates within zones or
  - ◆ 1 to 1 within zones

# Nodal exchange rate using MWkm methodology

---

- ◆ DCLF with various contingencies taken
- ◆  $X_{rate} = \frac{Cont(node\ 1) - Intact(node\ 1)}{Cont(node\ 2) - Intact(node\ 2)}$
- ◆ Advantage that some automation to pick up all circuits is available with Seculf
- ◆ No need for picking critical circuits
- ◆ Weaknesses –
  - ◆ MWkm does not equate to critical flow (exchange rates that are overestimated found)
  - ◆ Aggregated approximation of the incremental MWkm
  - ◆ No direct correlation to overloaded flow and hence increase in system operator cost

# Nodal exchange rate using MW methodology (NZM model)

---

- ◆ DC load flow using linearized sensitivities, hence no need for consideration of amount of trade
- ◆ Contingencies and critical circuits important (automation of all)
- ◆ Choice of slack bus important (all right if sufficiently away from analysis region but not always the case)
- ◆  $X_{rate} = \text{Sens}(\text{node 1}) / \text{Sens}(\text{node 2})$  – Note that worst case  $X_{rate}$  is then selected from all analysis
- ◆ Stable results – provides the exchange rates required to maintain current compliant status quo

# Nodal exchange rate using MW methodology (NZM model)

---

- ◆ Weaknesses –
  - ◆ Exchange rates that are quite onerous particularly when considering all contingencies and critical circuits
  - ◆ The non-symmetry of exchange rates mean that a particular region can lose all of its available TEC following a number of trades
  - ◆ No consideration of headroom and other measures (QB tapping, etc.) to remain compliant

# Questions that need answering

---

- ◆ Zonal methodology versus Nodal
- ◆ Intra-zonal trading?
- ◆ MW versus MWkm for exchange rates
- ◆ What is the extend of automation for nodal exchange rates
- ◆ Do we need to revert to SZM (Scenario based modelling) to enable consideration of headroom and provide link to cost of constraint analysis
